settings, it is important to have available information about lifetime risk for various age ranges for the remainder of life, so that women can be offered advice that is specific to their personal and family circumstances.

ACKNOWLEDGEMENT
The NSW Breast Cancer Institute receives financial support from the NSW Department of Health.

REFERENCES
melanoma of skin, colon and rectum were the five most common cancers in males (accounting for 61 per cent of all cancer in males). Cancers of breast, melanoma of skin, colon, lung and rectum were the five most common in females (accounting for 59 per cent of all cancers in females).

**TRENDS IN INCIDENCE AND MORTALITY**

Between 1987 and 1997, the incidence rates for cancer of all sites combined rose by 17 per cent for males and 11 per cent for females. The major contributors to this increase were prostate cancer and melanoma in males, and breast and lung cancer and non-Hodgkin’s lymphoma in females. Notable trends described in the report included the following:

- incidence rates for prostate cancer fell in 1997 following rapid increases between 1988 and 1994;
- incidence rates continued to fall for cervical cancer, there were fewer than 300 cases in 1997;
- there were falling incidence rates of some of the more common cancers that have low survival rates such as lung cancer, head and neck, and pancreatic cancer in males and stomach and bladder cancer in both males and females;
- the rate of lung cancer in females prior to the age of 50 years is now equal to that of males. Projections indicate that lung cancer rates in males and females will continue to converge with similar rates per 100,000 expected in 2006 (30.8 in males compared to 28.7 in females);
- there was a 16 per cent fall in age standardised mortality rates from breast cancer from 1987–1997;
- the incidence and mortality rates of liver cancer and mesothelioma have increased dramatically.
since the early 1970s, and are described in two new feature pages;
• when all cancers are considered together, mortality rates have fallen annually since 1987 by 1.3 per cent in males and 0.9 per cent in females. Age-adjusted mortality in both males and females was the lowest it has been since the Cancer Registry began operation in 1972;
• the large increases in the incidence of cancers of the prostate in males and breast in females have not been reflected in mortality rates;
• changes in mortality from stomach, pancreatic, liver, and lung cancers and mesothelioma are similar to those in incidence.

Figures 2 and 3 show the average annual changes in incidence and mortality from 1987 to 1997.
